

Requirement Analysis - Customer Journey Map Report

1. Executive Summary & Journey Scope

This Customer Journey Map illustrates the complete experience of an employee requesting network provisioning or relocating network infrastructure within the organization. It examines each stage of the user's interaction, from identifying the need for a network service to the successful completion of the request.

The analysis helps identify the limitations of the existing manual process and demonstrates how ServiceNow features such as the Service Catalog, UI Policies, Flow Designer, and custom database tables can automate the workflow, improve user experience, and increase operational efficiency.

2. Target Persona Profile

Persona Name: Abel Tuter

Role: Enterprise Employee / Corporate Requester

Scenario: A non-technical employee requesting a new network connection or relocating existing network equipment due to office movement or workspace changes.

Primary Objectives

- Submit network requests with complete and accurate information.
- Track the progress of the request throughout the approval and fulfillment process.

- Minimize delays and ensure uninterrupted network availability during workspace relocation.

3. Customer Journey Stages

Stage 1 – Identifying the Network Requirement

User Activity

The employee receives information about an upcoming office relocation or the need for a new network connection and searches the organization's intranet or support portal for the appropriate request process.

User Perspective

The employee expects an easy way to locate the correct network request service without depending on emails or multiple support channels.

User Experience

The lack of a centralized request portal creates uncertainty and confusion while identifying the correct submission process.

Existing Challenge

Network request instructions are distributed across multiple communication channels, making the process difficult to follow.

Proposed ServiceNow Solution

Provide a dedicated **Network Request Catalog Item** within the ServiceNow Service Portal, allowing employees to submit requests through a single, centralized platform.

Stage 2 – Request Submission

User Activity

The employee completes the request form by entering personal information, device details, and network location data.

User Perspective

The employee expects the system to automatically populate basic profile information and display only the fields required for the selected request type.

User Experience

Manual data entry and lengthy request forms increase the effort required to submit a request and may result in incorrect or incomplete information.

Existing Challenge

The current request form lacks auto-populated fields and dynamic field visibility.

Proposed ServiceNow Solution

Implement Client Scripts to automatically populate employee details and use UI Policies to display additional fields only when specific request types, such as network relocation, are selected.

Stage 3 – Approval and Request Tracking

User Activity

After submitting the request, the employee waits for approval and regularly checks the request status through emails or by contacting the IT support team.

User Perspective

The employee expects clear visibility into the approval process and timely updates on request progress.

User Experience

The absence of automated notifications and status tracking creates uncertainty and delays.

Existing Challenge

Approval requests are handled manually, resulting in limited transparency and delayed processing.

Proposed ServiceNow Solution

Configure Flow Designer to automatically route requests for manager approval, generate notifications, and display real-time request status updates within the Service Portal.

Stage 4 – Network Provisioning and Completion

User Activity

After receiving approval, the IT Network team completes the required network installation or relocation, and the employee verifies that the service is functioning correctly.

User Perspective

The employee expects the network service to be provisioned accurately and without delays.

User Experience

Although the request is eventually completed, manual data entry during earlier stages increases the possibility of configuration errors and deployment delays.

Existing Challenge

Manual recording of network information creates the risk of inaccurate data and inconsistent asset records.

Proposed ServiceNow Solution

Automatically transfer approved request details into the dedicated **u_network_database** table using Flow Designer, ensuring accurate record management and maintaining data integrity throughout the request lifecycle.
